Regeneration of deep intrabony periodontal defects with enamel matrix derivative: A case report

A clinical case of treatment of two severe intrabony defects on the aesthetic zone is reported and followed for one year.

The biomaterial of choice was enamel matrix derivative (Emdogain®; Straumann™) alone with a preservation papilla flap and a minimally invasive surgical technique.

After surgical treatment, the patient was kept in a supportive periodontal therapy programme with 6-month interval between appointments.

In the one year after surgery appointment, clinical and radiographic changes were observed, showing periodontal health and stability.
